Week 2: Bare Metal and the Boot Process

Bare Metal Programming

A conventional computing environment

• The standard applications that we run on our computers do so with the support of an underlying operating system:

- These applications benefit enormously from the functionality that the operating system provides:
 - Memory management
 - I/O
 - File systems
 - Networking
 - etc...

2				
3				

A bare metal environment

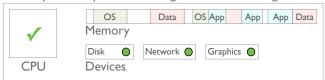

• What if we ran applications directly on the hardware, without an underlying operating system?

- Applications like this are said to be "running on the bare
 - Direct access to and manipulation of hardware
 - Potential to reduce complexity and cost
 - Less suited to general purpose computing ...
 - · Although conventional operating systems are bare metal systems that enable a general purpose environment

The boot process

• When your computer is running, it looks something like this:

- The CPU is initialized
- The memory contains the apps and data that we need
- The devices are initialized and operational
- · How did that happen?

Initializing the CPU

- The CPU will typically initialize itself when power is first applied or when the system is reset:
 - Basic self-test
 - Initialize registers to known states
 - ... including the instruction pointer/program counter
 - On IA32, for example, eip, is set to 0xFFFFFF0
- So the computer can begin executing programs ...
- And those programs can initialize the devices ...
- But only if those programs are in memory!

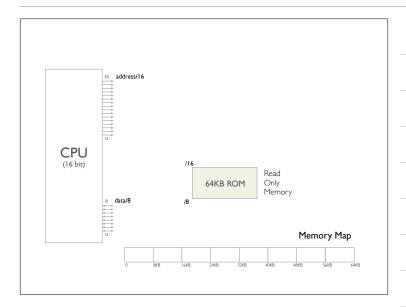

where does information come from?

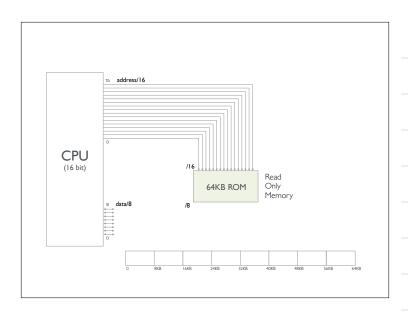

Building a Simple Computer System

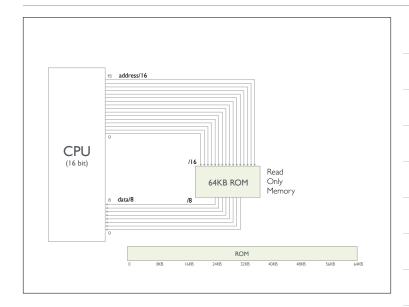

7

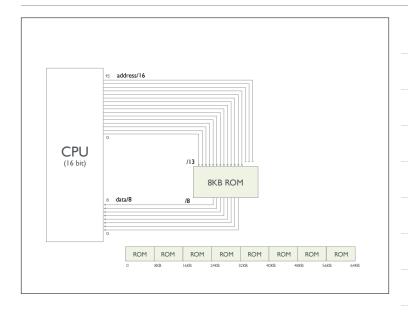

Building a basic computer system

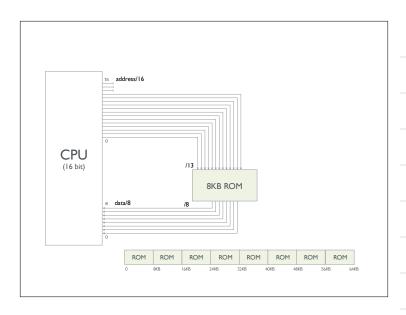

- Let's review some basic techniques that are used to construct a typical computer
- For the purposes of this exercise, we'll assume a 16 bit processor ... but the same ideas apply to other architectures
- Key goal: understand how physical memory might be organized and addressed

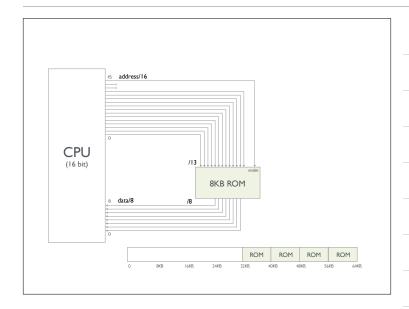

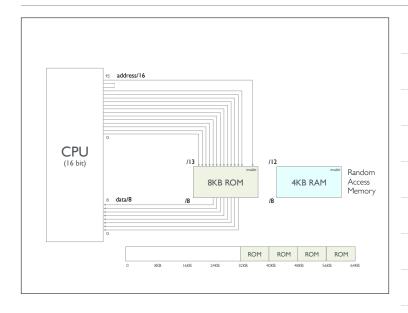

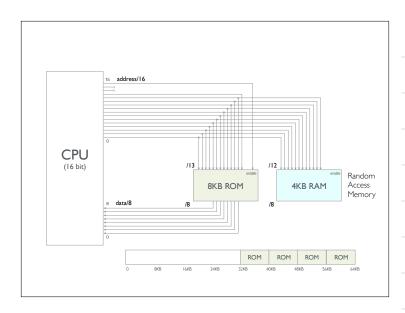

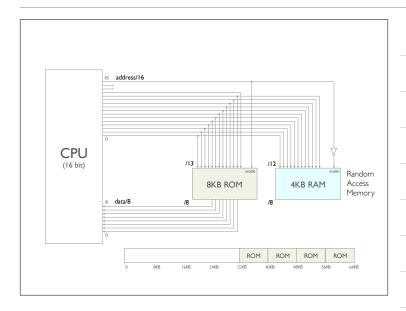

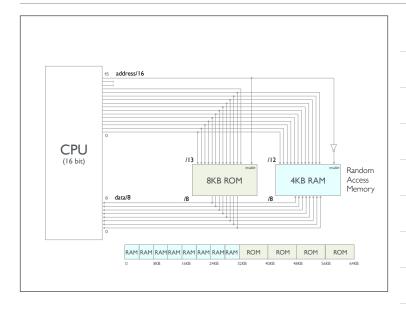

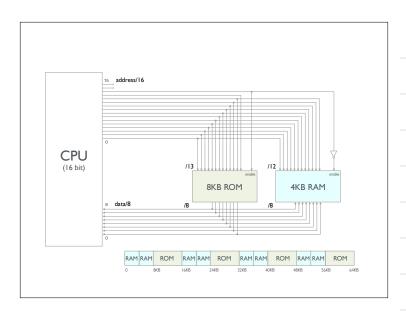

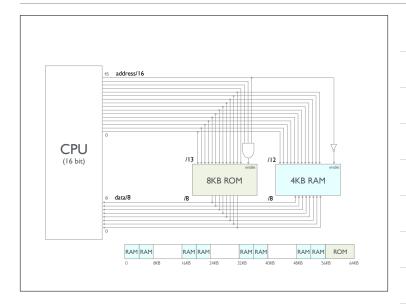

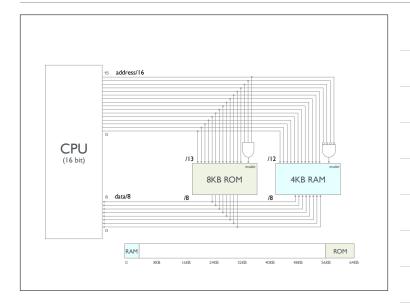

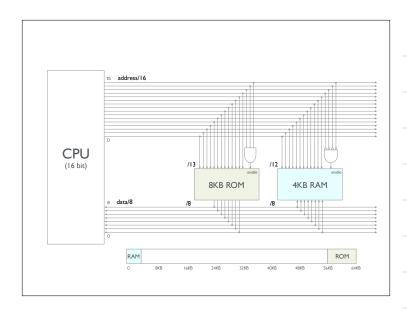

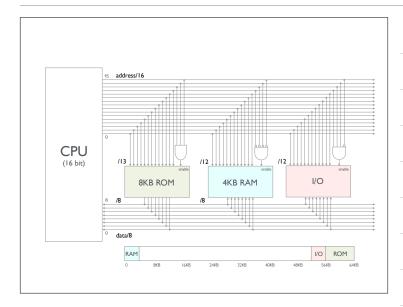

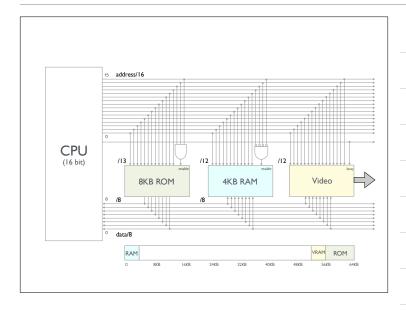

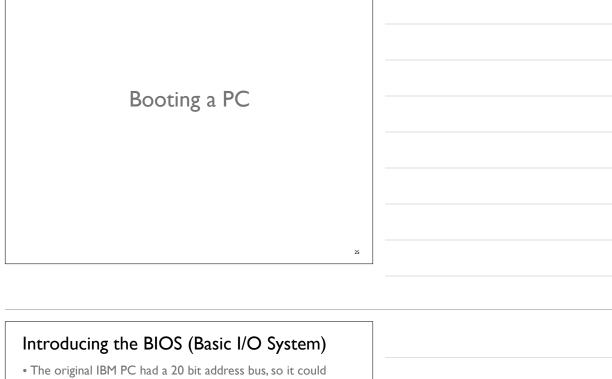

address up to IMB of data:

- The CPU starts executing programs at an address close to the top of the address space ...
- ... so we can install a ROM at that address:

• The ROM contains the BIOS, or basic I/O system, for the computer

... continued

• The rest of the address space can be used for RAM (who would need more than 640KB, eh?):

• Video RAM is also mapped within the region above 640KB (at address 0xb8000), so it doesn't interfere with lower memory:

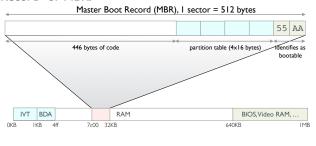

• But the BIOS does need to use some of that memory for its own purposes:

The master boot record (MBR)

- We don't want the BIOS to make too many assumptions about the operating system that it is booting
- Instead, the BIOS searches the available hardware for a "bootable" disk that contains a 512 byte "Master Boot Record" or MBR:

28

... booting, continued

- Now the program from the MBR can continue the process of loading the rest of the operating system ...
- ullet ... taking advantage of BIOS routines ...
- $\bullet \dots$ but without relying on a BIOS that is hardwired to that particular OS

29

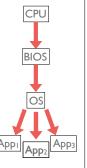

Boot loaders

Boot scenarios Custom hardware Simple, single purpose programmed system, app in ROM Single purpose programmed system, app on disk or other media

... continued

App on disk or media, leveraging an underlying operating system

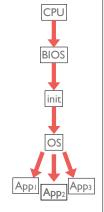

32

... continued

- Boot time configuration that is not required once the system is properly initialized
- Typical uses:
 - initialize and test a device
 - decrypt/decompress a file system
 - free resources (e.g., memory) that are not required once the system is booted

Potential to boot into one of multiple operating systems, selected at runtime The role of a boot loader is to: prepare the next stage to run (includes selecting between multiple possible "next stages") collect and pass on configuration details

Introducing GRUB

(The GNU GRand Universal Bootloader)

35

Booting via GRUB

• After reset, the CPU starts executing code in the BIOS ROM

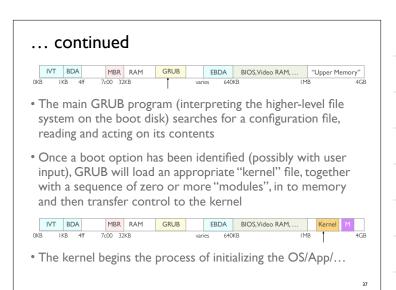

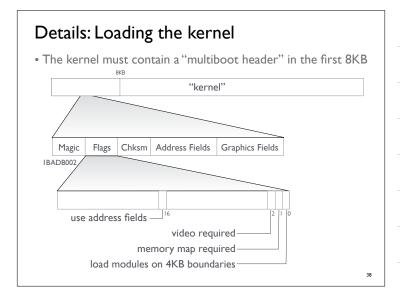

• The BIOS loads and transfers control to the MBR code

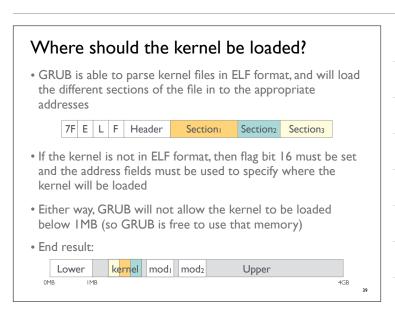

• The MBR code loads GRUB from a known location on the disk (using BIOS routines)

Kernel in control!

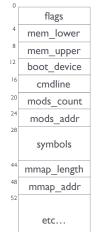

- GRUB's work is done, and it jumps to the specified entry point for the kernel:
 - eax will contain 0x2BADB002
 - ebx will contain the address of the "multiboot information structure"

- Values in other registers are also set to appropriate constant values, as described by the multiboot specification
- What will the "kernel" do next?

40

Multiboot Information

lower memory in KB (if flags[0]) upper memory in KB (if flags[0])

pointer to command line string (if flags[2]) number of modules (if flags[3]) address of first module descriptor (if flags[3])

length of memory map buffer (if flags[6]) address of first memory map entry (if flags[6])

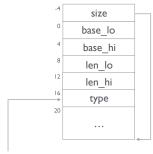

41

Multiboot Information, continued

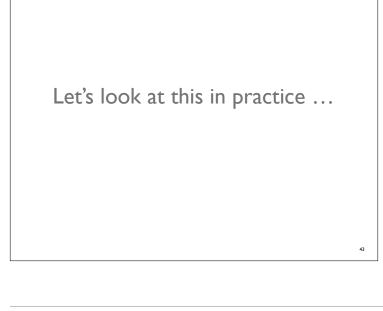

For each "module"

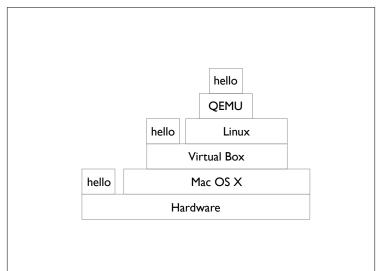

For each memory map entry:

type = I ⇒ available RAM

Installing the LLP virtual machine

Make your own VM

- Make a note of the machine you are using ...
- Create a directory for your virtual machine mkdir /disk/trump/cs410_LLP/\$USER
- In your home directory, run virtualbox
- Use "Preferences" to set default path for virtual machines to /disk/trump/cs410 LLP/\$USER
- Use "Import Appliance ..." to import the virtual machine at /disk/trump/cs410 LLP/llpVM.ova
- Sit back and wait ...

46

Connect to your LinuxLab account

- Create a directory for your LLP materials (I'm using ~/11p)
- Configure your directory as a shared folder of the VM

Caveats

- The VM you are creating is stored on the hard drive of the specific machine that you are using; it is not backed up and is not available from elsewhere.
- The contents of your Ilp folder are stored in your LinuxLab account, so they are backed up and accessible from other machines.
- I'm not completely clear about licensing restrictions on all of the files in the image/in the files that I share with you; please do not redistribute or post them on publicly accessible sites. Thank you!

Some objectives I. Write simple programs that can run in a bare-metal environment using low-level programming languages. Discuss common challenges in low-level systems software development, including debugging in a bare-metal environment using low-level systems software development, including debugging in a bare-metal environment. Describe the key steps in a typical boot process, including the role of a bootdoader. Portfolio pragmatics You've done work, learned some things, and can demonstrate that you've sastified some objectives what now? *What kind of work? *Carefully commented, tested code (source code in a tar file, zig file, no binaries, object code) *Wintten documentation (pdf. cxt) *Independent research/investigation/project/ *Upload the work item to your portfolio dropbox on D2L *Upload the work item to your portfolio dropbox on D2L *Upload the work item to your portfolio dropbox on D2L *Add a separate narrative, explaining how your work item(s) address (perhaps meet or exceed) a specific objective *Make your cast; make it easy for me to find and follow; make it easy for me to agree! .)	On your own machine?	
Some objectives 1. Write simple programs that can run in a bare-metal environment using low-level programming languages. 2. Discuss common challenges in low-level systems software development, including debugging in a bare-metal environment. 5. Describe the key steps in a typical boot process, including the role of a bootloader. Portfolio pragmatics * You've done work, learned some things, and can demonstrate that you've satisfied some objectives what now? What kind of work? * Carefully commented, tested code (source code in a tar file, zip file, no binaries, object code) *Written documentation (pdf. txt) * Independent research/investigation/project/ * Upload the work item to your portfolio dropbox on D2L * Add a separare armartive, explaining how your work item(s) address (perhaps meet or exceed) a specific objective * Make your case; make it easy for me to find and follow, make it easy for me to agree! :)	You can download virtualbox for free from virtualbox.org

Exercises	
 Add a function to the code for "hello" that can be used to output an integer value (hexadecimal notation is probably easiest, and most useful too). Test to make sure it works correctly 	
 Integrate your assembly code for cls into "hello" 	
 Adapt the code from "hello" or "bootinfo" to print out a summary of the details that GRUB passes on to the "kernel" via the multiboot information structure. (Start simple, and add more fields as you go.) 	
Experiment with different virtual machine settings to see what impact this has on the information in the multiboot structure.	
-	
Introducing mimgload and mimgmake	
mer o dad em 8 mm 8 marte	
53	
GRUB is great	
 It can load a "kernel" in one of several executable formats, as well as a collection of uninterpreted "modules" 	
 It supports booting from a variety of different media and file systems 	
It supports network booting	
It can load from compressed kernel/module images	
 It provides a boot-time menu and allows customization 	
 It gathers useful data about the machine and makes it available to the kernel 	
• Widely used, "multiboot standard", open source,	
54	

But, of course, it has limits too ...

- It can only load one executable
 - Possible workarounds include merging multiple ELF files into a single file, or using a kernel that can unpack executables from modules ...
- The address at which modules are loaded cannot be controlled or predicted
- The location of the multiboot information structures is not specified, and is not even guaranteed to be stored in a contiguous block of memory
- There are limits on where GRUB can load data (e.g., it does not appear to be able to load into lower memory)

55

Memory Images

 Think about what we want the memory layout to look like immediately after the boot process completes:

• Package up those components in a (compressed) module:

• Boot from GRUB into a small program that can unpack the image, move the pieces to the required locations (including boot data), and transfer control to the main program:

56

mimgmake and mimgload

• mimgmake builds image files (in a full Linux environment):

```
../mimg/mimgmake image
    noload:../mimg/mimgload \
    bootdata:0x0000-0x3fff \
    $(KERNEL)/pork \
    user/sigma0/sigma0 \
    user/l4ka-pingpong/pingpong
```

• mimgload loads images (on bare metal):

```
menuentry "InsertKernelNameHere" {
  multiboot /mimgload
  module /image.gz
}
```

 No particular claim to originality: this was just a tool that I built as a learning experience/to meet a practical need

The mimg file format

• Memory images are stored as binary files using a simple format that is like a greatly simplified version of ELF:

• Individual sections:

first	last	0	type	payload

- if type is DATA (1) or BOOTDATA(2), payload will contain (last-first+1) bytes
- if type is ZERO (0), or RESERVED (3), payload is empty
